**Abstract** The purpose of this study was to determine the effect of a 12-week, low-intensity, supervised exercise program on the health-related quality of life (HRQL) of patients with heart failure (HF). The study was a randomized, controlled trial. The study population consisted of 100 patients with HF who were randomly assigned to either a supervised exercise program or a control group. The supervised exercise program consisted of 12 weeks of low-intensity, supervised exercise. The control group received standard care. The primary outcome was the change in HRQL, measured using the EuroQOL-5D questionnaire. The secondary outcome was the change in clinical outcomes, including mortality and hospitalization. The results showed that the supervised exercise program significantly improved HRQL compared to the control group. There was no significant difference in clinical outcomes between the two groups. The study suggests that a supervised exercise program can improve the HRQL of patients with HF.
